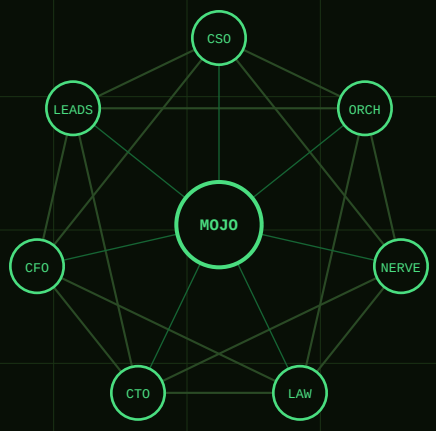
MojoBrain

Architecture Guide

How to Build a 7-Agent AI Operating System



eyshtech.vip | By Eysha Penrod

The Problem

You built a business. Now it's running you.

Every week you spend 15–20 hours on operations that have nothing to do with serving clients — follow-ups you forgot to send, invoices you haven't checked, that security setting you've been meaning to audit, the lead that replied three days ago and is now cold. You know the list. It haunts you on Sunday nights.

I know because I was you. I spent 6 years as a Google Workspace Sr. Account Manager at MarketStar, managing environments for 250+ SMBs. I watched the same pattern everywhere: smart business owners drowning in admin work that should run itself.

When I went out on my own, it got worse. I was the CEO, the IT department, the sales team, and the compliance officer — all at once. I almost hired a VA. Then I realized I'd just be managing the VA.

I remember the exact week it broke me. I had three client proposals sitting unfinished, a lead from Tuesday I hadn't followed up on, and I'd just discovered my SSL cert had expired three weeks ago and nobody told me. Not a tool. Not an alert. Nobody. Because there was nobody — it was just me. The lead from Tuesday? They'd gone with someone else by Thursday.

That was the week I stopped trying to work harder and started building something to work for me.

The math is brutal when you write it down. 15–20 hours a week on admin at even a conservative $75/hr billable rate — that's $1,125 to $1,500 a week you're spending on work that doesn't directly grow your business. Every week. That's before you count the leads that went cold, the invoices paid late, the security gaps you haven't had time to close.

I tried the usual answers. Hired a VA — spent more time managing her than she saved me. Signed up for every productivity app — now I had 12 tabs of tools to check instead of 8. Built Zapier automations — worked great until Zapier changed their pricing and my task budget ran out mid-month. None of it was the answer because none of it actually ran itself.

> 15-20 hours/week on ops x $75/hr billable rate
> = $4,500-6,000/month in lost revenue.
> MojoBrain costs ~$5-20/mo in API fees to run.

So I built MojoBrain. Seven autonomous AI agents that handle lead gen, outreach, compliance, finances, and security. Running 24/7 on a single Mac Mini. I approve from my phone every morning. The agents handle the rest.

I named it Mojo. It felt right.

What Actually Runs

Let me walk you through it. MojoBrain is a collection of Python scripts that run on cron schedules — every 5 minutes, every 15 minutes, every hour, depending on the agent. Each one writes to a JSON state file. No fancy framework. No Docker. Just Python, cron, and JSON.

Here's the thing about how they coordinate — none of them talk to each other directly. Everything goes through the Nerve Center. Every 5 minutes, the Nerve Center reads all agent outputs, builds a unified picture of what's happening across the entire system, and routes events between agents when something cross-functional happens. If the Lead Engine finds a hot prospect and the CSO notices that prospect's domain has a security issue — the Nerve Center connects those dots.

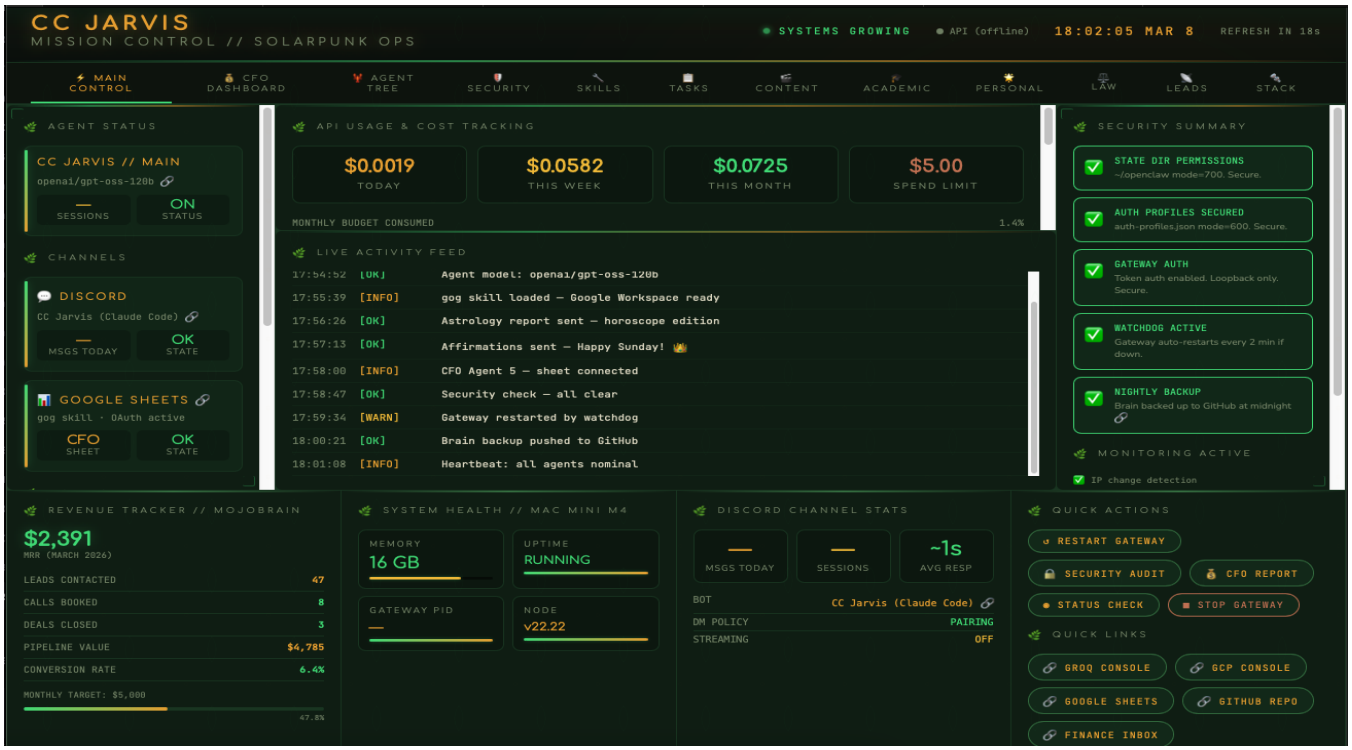
You get notifications via Discord. Critical stuff goes to one channel. Routine logs go to another. Morning briefings go to a third. You see what matters. Nothing more.

> By the time I wake up, the CSO has already run 8 security checks, the Lead Engine has scored overnight scrapes, and my morning briefing is waiting in Discord. I read it over coffee. Most days I approve two things and move on with my actual work.

Here's what my morning looks like now. I wake up. My phone has a Discord notification — the morning briefing my Orchestrator generated at 7am. It tells me: 3 new leads scored overnight (top one is 8/10, a logistics company in Marietta that just posted a Google Workspace admin role), 2 emails pending my approval, system health is green, no security alerts. I approve the emails from my phone. Done. That's my entire ops review. Takes four minutes.

Here's what I haven't done manually since deploying MojoBrain: checked my DNS records. Audited my Workspace permissions. Prospected for leads on LinkedIn at 10pm. Wondered if my SSL cert was still valid. Forgotten to follow up on a lead. Missed a tax deadline. The agents do all of it, every day, whether I'm awake or not. I just steer.

MISSION CONTROL — LIVE VIEW OF ALL AGENTS



Real output. Your Mission Control looks like this.

This is Mission Control — the dashboard every MojoBrain deployment includes. It's a single self-contained HTML file that runs on your local network. No cloud dependency. No login. Just open a browser tab and you see everything: which agents are running, what they found, system health, financial alerts, pending approvals.

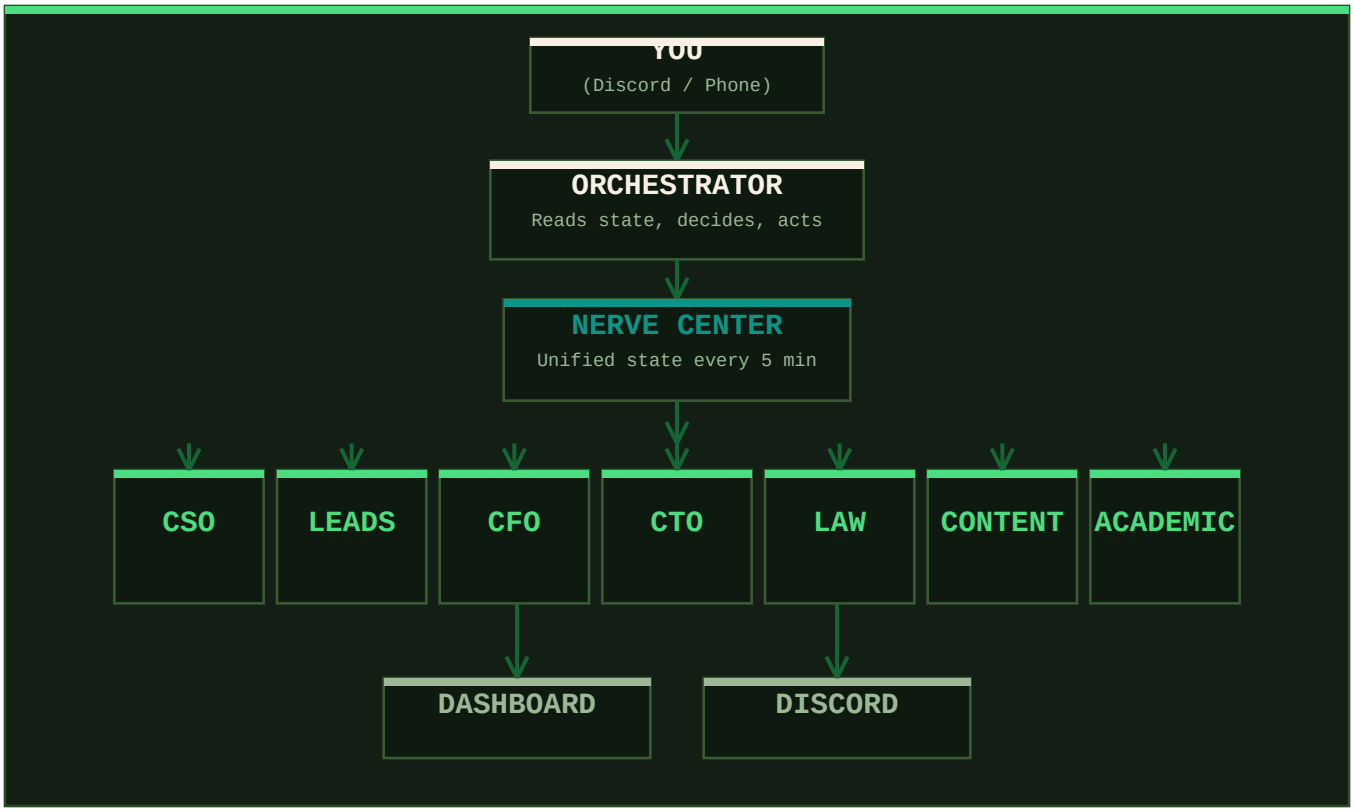
The top row shows critical alerts and blockers. The middle section tracks agent activity — green means healthy, yellow means stale, red means something needs attention. The bottom shows pending approvals that need your sign-off before agents act. I check it once in the morning and once before bed. That's it.

Every tier includes this dashboard. Managed Deploy clients get it branded with their logo.

How It All Connects

The architecture is deliberately simple. Complexity is the enemy of reliability — and when you're running a business on this system, reliability isn't optional.

SYSTEM ARCHITECTURE



You sit at the top. The Orchestrator reads the Nerve Center's unified state and decides what needs your attention. The Nerve Center reads all 7 agent outputs every 5 minutes. The agents run independently on their own cron schedules, writing to JSON state files. Everything flows down to the Dashboard (your visual command center) and Discord (your notification channel).

Every agent is isolated. They don't talk to each other directly — they write to their own state files, and the Nerve Center reads everything. This matters more than it sounds. It means if one agent crashes, nothing else breaks. The Lead Engine can be down for an hour and the CSO doesn't even notice.

I've had agents fail silently, miss a cron run, return junk data. The system keeps running. The Orchestrator detects the anomaly, logs it, alerts me if it's critical. Most of the time I find out about a failure in the morning briefing, already fixed. That's by design. If a system requires your constant attention to stay alive, it's not a system — it's a second job.

The 7 Core Agents

Think of them less like software and more like employees who never sleep, never forget, and never complain. Each one has a job, a schedule, and a personality. Here's who does what.

Orchestrator

CENTRAL INTELLIGENCE

The brain. Reads all agent outputs, makes decisions, routes events, and sends your morning briefing. The morning I woke up to a Discord message that said 'Lead Engine detected a high-value prospect — queuing outreach, confidence 9/10' — that was the moment I realized the Orchestrator wasn't just coordinating scripts. It was making business decisions. While I slept.

CSO

SECURITY

Paranoid in the best way. Checks DNS records, scans for breach mentions, audits SSL certs — every 15 minutes. Three weeks after deploying, it flagged that my SPF record had been misconfigured. Emails were hitting spam folders. I'd been sending cold outreach for two weeks to an audience that couldn't see it. The CSO caught it on a routine scan. I fixed it in 20 minutes. That one catch paid for the entire system.

Lead Engine

LEAD GENERATION

This is the one that paid for itself first. Last Tuesday it found a design agency in Kennesaw that had just posted three Google Workspace admin jobs. By 6am it had validated their domain, found the ops director's email via Hunter, scored them 8/10, and queued a personalized outreach email. I didn't touch any of it. That's the agent that replaced 15 hours of weekly prospecting.

Nerve Center

COORDINATION

This is the one most people underestimate. It's not flashy. It doesn't send you alerts or generate leads. It just reads everything, all the time, and builds a complete picture. The day it detected that my Lead Engine was generating leads faster than my CFO was tracking outreach costs — and flagged the discrepancy — I knew it was working exactly as intended. It's the difference between 7 independent tools and one coordinated brain.

CFO

FINANCE

It found a $49/month subscription I'd forgotten about. Software I'd signed up for during a free trial 8 months earlier. Never used it once. The CFO flagged it on a routine audit. $588/year I was just bleeding quietly. That's a boring story. It's also exactly the kind of story that adds up. It tracks your burn rate, monitors every subscription, flags suspicious charges, and knows your tax deadlines.

CTO

INFRASTRUCTURE

It caught a disk space issue at 2am that would have crashed the system by morning. Auto-cleared old logs, freed up 40GB, sent me a one-line summary. I read about it over coffee. That's the ideal outcome — I find out about problems after they're already solved. It monitors system health, cron jobs, and runs automated recovery protocols because things always go sideways at 3am.

Law

COMPLIANCE

Compliance is the agent most people want to skip. Don't. The day you get a GDPR inquiry or a CAN-SPAM complaint with no documentation is a bad day. The Law agent runs quietly, tracks your compliance state, flags anything that needs attention. It runs weekly audits against your public-facing pages and flags anything that's drifted. You hope you never need it. When you do, you'll be very glad it's there.

That's the team. Seven agents, each with a job, each running on a schedule, each reporting to the Nerve Center. They don't need motivation. They don't take sick days. They don't forget. And when one of them catches something — the SPF misconfig, the $49 subscription, the 2am disk space issue — it's not because you remembered to check. It's because the system never stops checking.

CC Jarvis deployments expand this to 15+ agents, customized to your specific business. But the 7 core agents above are the foundation everything else builds on.

What This Costs to Run

Here's exactly what this costs to run. I was shocked when I added it up the first time.

~$20	7	24/7
Monthly API Cost	Autonomous Agents	Unattended Operation

Component	Technology	Cost
Hardware	Mac Mini / Linux / VM	$0 (use yours)
LLM	Your choice (Claude, GPT, Groq)	$5-20/mo
Orchestration	Python 3 + cron	$0
Dashboard	Self-contained HTML	$0
Notifications	Discord webhooks	$0
Email	Brevo (5K emails/mo)	$9/mo
Remote Access	Tailscale	$0
Domain	Namecheap	$7/yr
Hosting	GitHub Pages	$0

The $0 cells aren't a trick. Groq gives you a genuinely useful free tier. Discord is free forever. GitHub is free for private repos. The only real cost is your LLM provider — and that's the brain that makes everything else work.

Why not just use Zapier?

I get this question a lot. Zapier, Make, n8n — they're all great tools. I've used them. But there's a fundamental philosophical difference between renting automation and owning your infrastructure.

Zapier is great until it isn't. The moment you hit a rate limit, or they change pricing, or they deprecate an integration you depend on, your entire business automation breaks. And you're stuck waiting for someone else to fix it. With MojoBrain, you own every line of code. If something breaks at 3am, you can fix it at 3am. Or better yet — your CTO agent fixes it for you.

The other thing nobody talks about: Zapier bills per task. When you're running 7 agents that each execute dozens of operations per day, those per-task costs add up fast. MojoBrain runs unlimited tasks for a flat API cost. The more your agents do, the more you save.

How I Got Here

MojoBrain didn't start as a product. It started as survival.

I was running a consulting business while employed full-time, managing tools manually, and losing leads because I couldn't follow up fast enough. I'd built this Frankenstein gateway thing — cobbled together from open-source tools, API proxies, and hope. It worked. Mostly.

Then it crashed at 3am on a Tuesday and took down everything. Not just the gateway — the crash triggered a cascade. The LLM proxy went down, which meant agent calls started failing, which meant the health checker started spamming restart attempts, which filled up the disk with error logs, which crashed the dashboard. I woke up to 178 error messages in my Discord.

That was the moment I decided to rebuild from scratch. Not fix it. Replace it.

> The first agent I built was the Lead Engine.
> Night one, it scraped and scored 47 leads while I slept.
> That one agent replaced 15 hours of manual prospecting per week.

The first morning after deploying the Lead Engine, I woke up to 23 scored leads waiting in Discord. I just sat there staring at my phone. It had done in one night what would have taken me two full days. And it ranked them — the ones most likely to buy were at the top. I'd never had that level of intelligence in my prospecting before.

Within two weeks I had 7 agents running. The system evolved from a collection of scripts into something that felt alive — a coordinated operating system with a central nervous system, a dashboard, and autonomous decision-making.

> The breakthrough wasn't any single agent.
> It was the Nerve Center — the component that reads ALL agent
> outputs every 5 minutes and coordinates cross-agent responses.
> That's when it stopped being scripts and became a system.

The first morning after deploying the Lead Engine, I woke up to 23 scored leads waiting in Discord. I just sat there staring at my phone. It had done in one night what would have taken me two full days of manual work. I approved three outreach emails from bed. By 9am, one had already been opened. That was the moment I stopped thinking of MojoBrain as a project and started thinking of it as infrastructure.

Everything I tried before MojoBrain was clever. The OpenClaw gateway was clever. The Zapier flows were clever. The VA arrangement was clever. MojoBrain is boring. Python scripts. Cron jobs. JSON files. Discord webhooks. Technologies that have existed for 20 years and will exist for 20 more.

There’s no magic here — just reliable primitives doing simple jobs on a schedule.

Boring is the point. Boring doesn’t crash at 3am. Boring doesn’t have a pricing tier that doubles next quarter. Boring just runs.

BEFORE CC JARVIS ———— AFTER CC JARVIS

178 errors in one hour vs. clean morning briefing. Same system, rebuilt right.

I’m telling you this because if your system is currently broken, the answer is probably not to fix it. It’s to replace it with something simpler.

The system I run today looks nothing like what I started with. The gateway is dead. The Zapier flows are dead. The VA is long gone. What survived is the boring stuff — Python scripts on cron, writing JSON, sending Discord webhooks. That’s the entire stack. And it’s been running without a critical failure for weeks.

If you take one thing from this story: don’t build what’s impressive. Build what’s reliable. The impressive version crashed at 3am and sent me 178 error messages. The boring version wakes me up with a clean briefing and a scored lead list. I’ll take boring every single time.

Start Here

The first agent I'd build if I were starting over is the security monitor. Not because it's the flashiest — it's not. But because it runs silently in the background and one day it's going to catch something that would have cost you real money or real embarrassment. Here's how to build all three.

01 — System Health Monitor

Before you start, you need: Python 3 installed, a Discord server with a webhook URL, and the psutil library (pip install psutil). That's it.

The script checks three things: disk space (alert if below 10%), memory usage (alert if above 90%), and whether your other cron jobs actually ran (check log file timestamps). It writes a status JSON file every run, and pings Discord only when something is wrong.

The key decision: how often to run it. I started with every hour. Within a week I moved it to every 15 minutes. When your server is your business, 45 minutes of undetected downtime is 45 minutes too many.

Watch out for false positives. macOS reports disk usage differently than Linux, and if you're running Time Machine backups, your disk will look "full" when it isn't. Add exclusions for known safe states.

Success looks like: you stop worrying about your infrastructure. You just trust that if something breaks, you'll know within 15 minutes. That peace of mind is worth more than the 30 minutes it takes to build.

```
Stack: Python + psutil + Discord webhook
  Schedule: */15 * * * *
  Build time: 30 minutes
```

02 — Morning Briefing Bot

You need: API access to whatever tools you use daily (email, calendar, task manager), plus a Discord webhook or email sender. The briefing bot pulls data from your tools and formats it into a human-readable summary.

Start simple. Mine started with three sections: email count, today's calendar, and overdue tasks. Over time I added weather, lead pipeline status, and financial alerts. Don't try to build the full version first — start with whatever makes your morning better and add from there.

The key insight: this agent changed my relationship with my phone. Instead of opening five apps and piecing together my day, I open Discord and it's all there. Formatted. Prioritized. Ready. It's like having a chief of staff who works for free and never calls in sick.

```
Stack: Python + cron + API calls
  Schedule: 0 11 * * * (7am ET)
  Build time: 1 hour
```

03 — Lead Scraper + Scorer

This is the one that makes money. Before you start, define your ideal customer profile — industry, company size, tech stack, geography. The more specific, the better the results. “Small businesses” is too broad. “Marketing agencies with 5-20 employees that use Google Workspace” is perfect.

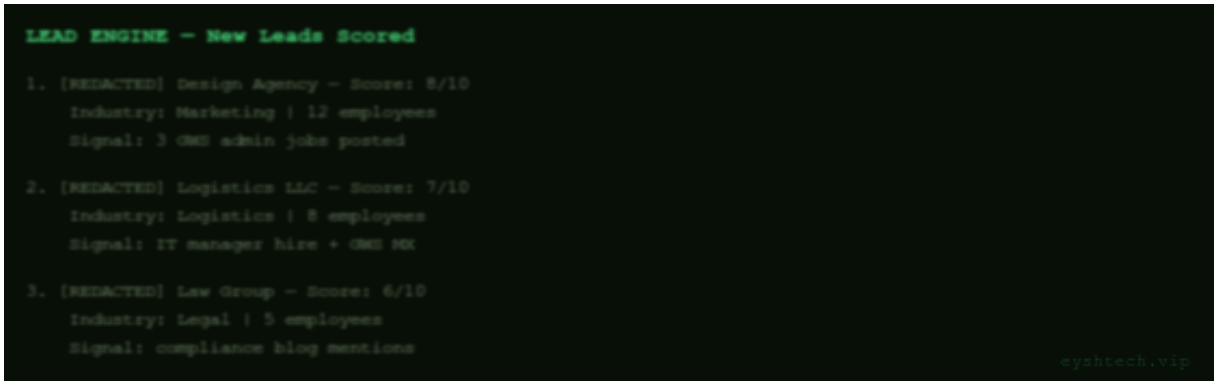
The script searches DuckDuckGo (no API key needed) for businesses matching your criteria, validates their domains with DNS checks (kills parked/dead domains before you waste time), and scores them on signals like recent hiring posts, tech stack indicators, and company size. The output is a ranked JSON file that your morning briefing can read.

The decision that matters most: your scoring weights. I spent a week tuning mine. Hiring posts for IT roles are a strong signal. A company blog that hasn’t been updated in 2 years is a weak one. Don’t overthink it on day one — deploy, review the results, and adjust the weights based on which leads actually convert.

Watch out for rate limiting. DuckDuckGo will throttle you if you fire 200 searches in a minute. Add delays between requests. I run mine at 2am when there’s no competition for bandwidth.

```
Stack: Python + DuckDuckGo + DNS checks
  Schedule: 0 6 * * * (2am ET)
  Build time: 2-3 hours
```

WHAT LANDS IN DISCORD EVERY MORNING AT 7AM



Real lead scores. Real industries. Names redacted for client privacy.

Where to Go From Here

If you've read this far, you're probably one of two people.

Either you're going to build this yourself — great, the patterns are all here. The three agents above are a real starting point, not a teaser. Build them this weekend and you'll have a system that's already better than what 90% of businesses are running.

Or you're thinking "I want this but I don't want to build it."

A word on DIY vs done-for-you

If you're comfortable in a terminal and have a weekend to spend — build it. Seriously. The patterns are all here and the satisfaction of watching your first agent run autonomously is genuinely one of the best feelings in tech. You'll stay up until 2am not because you have to, but because you can't stop adding features.

If you're not technical, or you just want it running by next week — that's what the paid tiers are for. No judgment either way. Different people need different things. I've built MojoBrain for both kinds of people.

Three ways to work together:

Playbook — $297	All 7 agent scripts, Mission Control dashboard, deployment playbook with video walkthroughs. You deploy it yourself on your own hardware. You own it forever.
Guided Setup — $797	Everything in Playbook plus a 2-hour live setup call, your Lead Engine customized to your specific market, cold email templates, the full skills library, and 30 days of Discord DM support. Most people pick this one.
Managed Deploy — $1,497	I install everything on your machine, configure all 7 agents for your business, build 3 custom agents for your specific workflow, and support you for 90 days. You just show up and approve.

Not sure which one? Start with a $97 Workspace audit. Thirty minutes, actionable recommendations, and the $97 applies as credit if you go with any MojoBrain tier. It's the lowest-risk way to see if we're a good fit.

> Currently onboarding 3 clients per month.

About

I'm Eysh. I spent 6 years as a Sr. Account Manager for Google Workspace at MarketStar — which means I spent 6 years watching small businesses struggle with the same operational chaos, over and over. The same missed follow-ups. The same security gaps. The same "I'll get to it next week" that turns into never.

When I went out on my own, I built the system I wish my clients had always had. MojoBrain runs in production daily, managing my own business operations. Seven agents, one machine, zero downtime. I sell the same system I depend on.

If something in this guide resonated — let's talk.
